SAP PS Interview Q&A – Sample Copy

30 SAP Project System interview questions with model answers, drawn from four topic banks: Costs and Budgets, Materials, Revenues and Earnings, and Structures.

At a glance

Every question is tagged `BEGINNER`, `INTERMEDIATE` or `ADVANCED`, so you can see the difficulty at a glance.

Topic	Beginner	Intermediate	Advanced	Total
Costs & Budgets	3	3	2	8
Materials & Procurement Integration	3	3	2	8
Revenues & Earnings	3	2	2	7
Structures (WBS & Networks)	3	2	2	7
Total	**12**	**10**	**8**	**30**

Costs & Budgets

Q1. What are the four primary methods of Cost Planning available in SAP PS?

`BEGINNER`

Answer: SAP PS supports four progressive levels of cost planning depending on the project's maturity stage:

1. Hierarchical Cost Planning (CJ40): Rough-cut, structure-oriented planning where the PM enters lump-sum estimates directly onto WBS Elements without needing Cost Elements.
2. Cost Element / Activity Input Planning (CJR2): Detailed primary cost and internal activity planning by Cost Element (G/L Account) and Fiscal Period on WBS Elements.
3. Easy Cost Planning (ECP) (CJ9ECP / CJ20N): Questionnaire-driven, form-based costing using predefined Costing Models.
4. Network Costing (CJ20N): Granular, automated bottom-up costing calculated from Network Activities (Work Centers) and Material Components (BOMs/MM).

Q2. What are the core Budgeting transaction codes in SAP PS (CJ30 to CJ38), and when is each used?

`BEGINNER`

Answer:

- CJ30 (Change Original Budget): Used once at project inception to enter the initial approved baseline budget.
- CJ31 (Display Budget): Read-only view of the project budget.

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

- CJ32 (Change Budget Release): Releases portions of the approved budget in tranches for spending.
- CJ34 (Budget Transfer): Moves budget laterally or vertically between WBS Elements (either within the same project or across two different projects) with a net zero change to total corporate budget.
- CJ36 / CJ37 (Budget Supplement): Adds new incremental budget to a WBS Element (within a project CJ37 or to a single WBS CJ36) when scope increases.
- CJ38 (Budget Return): Removes excess unspent budget from a WBS Element and returns it to corporate funds.

Q3. What is "Project Settlement" (CJ88 / CJ8G), and why is it mandatory at period-end?

`BEGINNER`

Answer: WBS Elements and Networks are temporary cost collectors. At month-end or project completion, the costs (and revenues) collected on the project must be transferred to their final accounting destination using CJ88 (Individual Settlement) or CJ8G (Collective Settlement) based on each WBS Element's Settlement Rule:

- Overhead / R&D Projects: Settle expenses to a Cost Center (CTR) or G/L Account (G/L).
- Capital Investment Projects: Settle capitalizable costs to an Asset under Construction (AuC) during construction, and to a Completed Fixed Asset (FXA) upon completion.
- Customer Revenue Projects: Settle calculated WIP, Revenue, and Cost of Sales to Profitability Analysis (PSG / Margin Analysis).

Q4. What is the difference between transactions CJBN and CJEN, and when do you run them?

`INTERMEDIATE`

Answer: These are the two most important diagnostic/reconstruction transactions in SAP PS Controlling:

- CJEN (Reconstruct Project Info Database): Rebuilds summary table RPSCO from the underlying CO/FI line items (COEP/COSP in ECC, or refreshes legacy plan/statistical buffers in S/4HANA) and Commitment tables (COOI). You run CJEN when standard S_ALR_* or CJE0 hierarchy reports do not match CJI3 line items.
- CJBN (Reconstruct Availability Control): Recalculates the AVC Assigned Values and Budget Ledger tables (BPGE/BPJA) from RPSCO. If you change a WBS hierarchy (PRHI), change Exempt Cost Elements in OPTK, or change tolerance limits, you must run CJEN first, followed by CJBN!

Q5. How do you preserve a frozen "Baseline Cost Plan" in SAP PS before modifying the live Cost Plan (Version 000) during project execution?

`INTERMEDIATE`

Answer: Because live execution and Network Costing continuously update CO Plan Version 000, controllers take a snapshot of the approved initial plan using transaction CJ9C (Copy Project Cost Plan - Collective) or CJ9CS (Individual):

1. Source Version = 000 (Current Operative Plan).
2. Target Version = 001 (Baseline Plan).

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

3. In transaction OKEQ (Maintain CO Versions), lock Fiscal Year settings for Version 001 ("Version Locked" checkbox) so no user can ever overwrite Version 001. Standard reports can then compare Version 001 (Baseline) vs. Version 000 (Current Forecast) vs. Actuals.

Q6. Why must Results Analysis Cost Elements (Cost Element Category 31) be exempted from Availability Control in OPTK?

`INTERMEDIATE`

Answer: On customer revenue projects (or WIP projects), running Results Analysis (KKA2) or S/4HANA Event-Based Revenue Recognition (EBRR) calculates Work in Process (WIP), Reserves for Unrealized Costs, and Cost of Sales, posting them to the Billing WBS Element under Results Analysis Secondary Cost Elements (Category 31). Because these Category 31 postings are purely accounting accruals/valuations derived from existing actual costs, if they are not exempted in transaction OPTK, Availability Control will treat the WIP/RA postings as new actual expenses, double-counting the project's spend and throwing false BP603 budget overrun errors during month-end closing!

Q7. How has the unification of G/L Accounts and Cost Elements in SAP S/4HANA (FS00) impacted PS Cost Planning, Overhead, and Settlement configuration?

`ADVANCED`

Answer: In classic SAP ECC, Primary Cost Elements (KA01) and Secondary Cost Elements (KA06) were maintained separately from FI G/L Accounts (FS00) in tables CSKA/CSKB. In SAP S/4HANA, KA01, KA02, and KA06 are obsolete and permanently redirected to FS00 (Manage G/L Account Master Data) (table SKA1/SKB1):

1. Primary Cost Elements: Created in FS00 with G/L Account Type P (Primary Costs or Revenue) and Cost Element Category 1 (Expenses) or 11 (Revenue).
2. Secondary Cost Elements: Created in FS00 as genuine G/L Accounts with G/L Account Type S (Secondary Costs) and Categories 21 (Internal Settlement), 41 (Overhead), 42 (Assessment), or 43 (Internal Activity Allocation)! Because Secondary Cost Elements are now real G/L Accounts in ACDOCA, every internal activity confirmation (CN25), overhead run (CJ44), and internal project settlement (CJ88) posts directly to the Universal Journal (ACDOCA) with zero FI-CO reconciliation needed!

Q8. How do you use the Availability Control Analysis diagnostic tool (CJ31 -> Extras -> Availability Control -> Analysis) to debug why AVC is blocking a posting?

`ADVANCED`

Answer: Whenever a user reports an unexpected BP603 / BP604 budget error, a PS consultant opens CJ31 (or CJ30) for the project and navigates to Extras -> Availability Control -> Analysis (or runs program BPFCTRA0):

1. The screen displays the exact Budget Bearing WBS Nodes (highlighting which superior WBS is actually enforcing the check).

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

2. Clicking the "Assigned Values" breakdown icon on that WBS displays the exact mathematical composition of the AVC check: how much comes from Actuals, Commitments (COOI), Plan of Apportioned Orders/Networks, and Subordinate Distributed Budgets.
3. Clicking "Cost Element Check" reveals exactly which Cost Elements were included vs. exempted via OPTK, immediately pinpointing the root cause in 30 seconds.

Materials & Procurement Integration

Q9. What is the difference between a "Material Reservation" (RESB) and a "Purchase Requisition" (EBAN) generated from a PS Network?

`BEGINNER`

Answer:

- Material Reservation (RESB): An internal warehouse demand document requesting the warehouse clerk to set aside a specific quantity of a stocked material and issue it (MIGO) to the Network Activity on its Requirement Date. A reservation does not go to an external vendor; instead, MRP reads the reservation and decides whether to buy or manufacture more stock.
- Purchase Requisition (EBAN): An external purchasing demand document instructing the MM Purchasing department to buy a specific quantity of a non-stock material (or direct-procurement stock material) from an outside vendor by converting the PR into a Purchase Order (ME21N).

Q10. Which Movement Types are used in MIGO to issue materials to a Project from general Plant Stock versus from Project Stock (Q)?

`BEGINNER`

Answer: When a warehouse clerk issues physical materials to a project in MIGO (Goods Issue):

- From General Plant Stock (No Special Stock Indicator):
  - 221: Goods Issue from Plant Stock directly to a WBS Element (222 = Reversal).
  - 281: Goods Issue from Plant Stock to a Network Activity (282 = Reversal).
  - 261: Goods Issue from Plant Stock to an Order / Network (262 = Reversal).
- From Segregated Project Stock (Special Stock Indicator Q):
  - 221 Q: Goods Issue from WBS Project Stock Q to a WBS Element.
  - 281 Q (or 261 Q): Goods Issue from WBS Project Stock Q to a Network Activity. (Crucially, Movement Type 281 Q ensures that the stock is deducted specifically from that WBS Element's segregated Q inventory in table MSPR/EBEW!)

Q11. What is "Backflushing" (RESB-RGEKZ) for a Network Material Component, and how does it automate Goods Issue during confirmation (CN25)?

`BEGINNER`

Answer: Normally, consuming a stocked material component on a project requires a two-step process: the warehouse clerk posts a manual Goods Issue in MIGO (261/281), and the engineer confirms labor hours in CN25. If the "Backflush" (RGEKZ) checkbox is ticked on the Material Component in CJ20N (or defaulted from the Material Master MRP 2 view / Work Center), the manual MIGO step is eliminated!

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

The exact moment the engineer saves a time/yield confirmation for the parent Network Activity in CN25, SAP automatically posts the Goods Issue (261 / 281) in the background, deducting the inventory from the storage location and debiting the actual material cost to the WBS Element/Network in one atomic step.

Q12. How does "Project MRP" (MD51) differ from standard Plant MRP (MD01N / MD02), and why is it critical for Engineer-to-Order (ETO) projects?

`INTERMEDIATE`

Answer:

- Plant MRP (MD01N in S/4HANA / MD01 in ECC): Plans all materials across an entire Plant, stepping through global Low-Level Codes. Running it mid-day for a single urgent project is too broad, and running single-item MD02 only plans one material hierarchy at a time.
- Project MRP (MD51 — Multi-Level Project Planning): Takes a Project Definition or WBS Element(s) as its selection input! MD51 scans every Network Reservation (RESB) assigned to the selected WBS Elements, identifies all components managed in Individual Project Stock (Q), explodes their multi-level BOMs across all levels for that WBS segment, and generates the required Planned Orders (PLAF) and Purchase Requisitions (EBAN) exclusively for that project in seconds!

Q13. When a Network has 50 activities requiring the exact same non-stock material, how does "Collective Purchase Requisitions" / "Material Bundling" consolidate them?

`INTERMEDIATE`

Answer: Normally, if 50 Network Activities each have a Non-Stock Material Component (Item Category N) for 10 bags of special mortar, releasing the Network generates 50 separate Purchase Requisition numbers (or 50 items) in EBAN. To streamline purchasing:

- In the Network Profile (OPUU) / Network Header: Enabling Collective Purchase Requisitions ensures that all non-stock components within the same Network share a single overarching Purchase Requisition number (EBAN-BANFN) with multiple line items (BNFPO = 0010, 0020...), rather than 50 separate PR headers!
- In CNMM (ProMan) or ME59N: Buyers can highlight all 50 PR items across the project and bundle them into a single Purchase Order (ME21N) with one click.

Q14. How do you configure the "Checking Control for Networks" in transaction OPJK to block Network Release if material components are missing (MSPT)?

`INTERMEDIATE`

Answer: In transaction OPJK (Define Checking Control for Networks), select the Controlling Area/Plant and Network Type combination:

1. Under Availability Check, specify whether the check should run during network creation (1) or network release (2).

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

2. Set the behavior parameter to No Release if Parts are Missing (or configure a user decision / warning). When active, attempting to change a Network Activity status to REL when an ATP check (MD04) shows a shortfall will trigger error V1307 or RU380, strictly blocking the release.

Q15. A user deletes a Material Component or sets TECO on a Network in CJ20N, yet an "orphaned" Reservation (RESB) or Purchase Requisition (EBAN) still appears in MD04 and locks up WBS budget. How do you diagnose and fix it?

ADVANCED

Answer: Occasionally, an update termination (SM13), lock collision, or flawed custom BAdI code in NETWORK_UPDATE causes RESB (XLOEK deletion flag) or EBAN/COOI to fall out of sync with the Network status. Never edit RESB or COOI via direct SQL! Instead, run the standard SAP PS/MM reconciliation programs in SE38 / SA38:

1. RLORD035: Reconciles and cleans up inconsistent or orphaned Purchase Requisitions (EBAN) and Reservations (RESB) for PS Networks.
2. SDRQCR21 (or RMMDVM20): Reconstructs material requirements (RESB) so phantom reservations disappear from MD04.
3. RKANBU01: Reconstructs open PR and PO Commitments (COOI) for the WBS Element/Network, followed by CJEN and CJBN to restore the locked WBS Available Budget!

Q16. How has the SAP S/4HANA Fiori app "Manage Project Demand" (F2947) transformed material procurement for WBS-only projects without Networks?

ADVANCED

Answer: In classic SAP ECC, triggering Material Reservations (L) or Non-Stock PRs (N) from SAP PS forced the creation of a PS Network and Network Activity inside CJ20N. In SAP S/4HANA (EPPM), the Fiori app "Manage Project Demand" (F2947) decouples logistics demand from User-Visible Networks:

1. Project managers working on WBS-only Enterprise Projects create a Material Demand (Stock or Non-Stock) or Service Demand and assign it directly to a WBS Element (Work Package) in a Fiori web screen.
2. When the user sets status to Requested / Released, S/4HANA's backend demand engine (I_ProjectDemandTP / OData API API_PROJECTDEMAND) automatically generates the underlying Purchase Requisition (EBAN) or Material Reservation (RESB) in the background, tracking fulfillment synchronously.

Revenues & Earnings

Q17. What are the three primary methods to plan Revenues on a Project in SAP PS?

BEGINNER

Answer: SAP PS supports three distinct ways to establish a project's Revenue Plan:

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

1. Structure-Oriented (Hierarchical) Revenue Planning (CJ42): The project manager manually enters lump-sum planned revenue figures directly onto Billing WBS Elements overall and by fiscal year (stored in tables BPGE/BPJA with Value Type 02).
2. Cost/Revenue Element Planning (CJR2 / Fiori Import Financial Plan Data): Detailed revenue planning by specific Revenue Cost Element (Category 11) and Sales Deduction Cost Element (Category 12) across fiscal periods (stored in COSP in ECC / ACDOCP in S/4HANA).
3. Automatic Revenue Plan Transfer from SD (VA21 Quotation / VA01 Sales Order): When an SD Quotation or Sales Order item is assigned to a Billing WBS Element, SAP automatically transfers the net item value and billing schedule dates from SD directly into the WBS Element's Revenue Plan!

Q18. Why does SAP PS enforce the "Single Billing Element per Vertical Branch" rule in a WBS hierarchy?

`BEGINNER`

Answer: Within any single vertical path (branch) of a WBS hierarchy, only one WBS Element can be flagged as a Billing Element (FAKKZ = 'X'). If Level 1 WBS P-100 is flagged as a Billing Element, SAP forbids flagging its subordinate child P-100.01 or grandchild P-100.01.01 as a Billing Element. Architectural Reason: Results Analysis (KKA2) and S/4HANA Event-Based Revenue Recognition (EBRR) dynamically roll up all actual and planned costs from the entire subordinate WBS subtree to the Billing WBS Element to calculate Percentage of Completion (PoC) and Work in Process (WIP). If two Billing Elements existed in the same vertical parent-child path, subordinate costs would be rolled up and counted twice! (Note: Multiple sibling WBS Elements at Level 2—such as P-100.01, P-100.02, and P-100.03—can all be Billing Elements, provided their parent Level 1 P-100 is NOT a Billing Element!)

Q19. What is "Resource-Related Billing" (Time & Material / Cost-Plus Billing via DP90 / DP91), and when is it used instead of Milestone Billing?

`BEGINNER`

Answer: While Milestone Billing charges a pre-agreed fixed price per phase, Resource-Related Billing (DP90 for Sales Orders / DP91 for Service Orders) is used for Time & Material (T&M) or Cost-Plus contracts where the customer pays for the actual labor hours worked, materials consumed, and travel expenses incurred on the project:

1. Throughout the month, employees confirm hours (CAT2/CN25), warehouse staff issue materials (MIGO), and AP posts vendor invoices (MIRO/FB60) to the project's WBS Elements and Networks.
2. At month-end, the project controller runs transaction DP90, which reads all unbilled actual cost line items via a DIP Profile (ODP1), applies contractual markups or rate-card prices, and generates an SD Debit Memo Request (L2 / RK).
3. Approving and billing the Debit Memo Request (VF01) invoices the customer for the exact resources consumed and posts the revenue back to the Billing WBS Element!

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

Q20. In ODP1 (DIP Profile Configuration), what is the difference between Source 0001 (Actual Costs - Line Items) and Source 0002 (Actual Costs - Totals Records), and when must you use 0001?

`INTERMEDIATE`

Answer: Under the Sources node of a DIP Profile in ODP1, you tell DP90 which CO tables to read:

- Source 0002 (Actual Costs - Totals Records — COSP/COSS in ECC): Reads pre-aggregated monthly totals by Cost Element and Activity Type. It is fast for high-volume projects, but you lose all line-item granularity (you cannot see individual employee personnel numbers, posting dates, vendor numbers, or line-item texts!).
- Source 0001 (Actual Costs - Line Items — COEP in ECC / ACDOCA in S/4HANA): Reads every individual financial/controlling document line item. When you MUST use 0001: Whenever the project manager needs to interactively Bill, Postpone, or Write Off individual expense documents or timesheet entries in DP90's Expenditure View, filter by Posting Date (mid-month cutoffs), or copy line-item descriptions onto the customer's invoice!

Q21. What is the difference between "Deleting Results Analysis Data" (KKA8 / KKA9) and reversing a Settlement (CJ88) when an RA Key was assigned to a WBS Element by mistake?

`INTERMEDIATE`

Answer: Suppose a consultant accidentally assigned a Results Analysis Key to an internal overhead WBS Element, ran KKA2 (which created WIP in COSB), and settled it via CJ88:

1. Step 1 — Reverse Settlement (CJ88 -> Settlement -> Reverse): First, reverse the CJ88 settlement run so the FI/CO-PA WIP postings are reversed. (However, reversing CJ88 does not clear table COSB, and SAP will block you from removing the RA Key from CJ20N with error KJ 129 "Results analysis data exists"!)
2. Step 2 — Delete Results Analysis Data (KKA8 Individual / KKA9 Collective): Run transaction KKA8 for the WBS Element and select the Results Analysis Version. KKA8 physically deletes the COSB and COEPB (Value Type 31) records for that WBS Element, unlocking the Results Analysis Key field in CJ20N so you can blank it out!

Q22. How does SAP S/4HANA Predictive Accounting (Extension Ledger 0E in ACDOCA) process Incoming Sales Orders (VA01) assigned to a Billing WBS Element, and how does it improve upon classic Value Type 25 Incoming Orders?

`ADVANCED`

Answer:

- Classic ECC Incoming Orders (Value Type 25): Required special configuration (OKG2/OPSA with Category 50/51 Cost Elements), wrote only to CO tables (COSP/RPSCO), and could only show the gross Sales Order value—it could not predict the expected Cost of Goods Sold, tax, or FI G/L impact!
- SAP S/4HANA Predictive Accounting (Extension Ledger 0E):

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

a. The moment a Sales Order (VA01) assigned to a Billing WBS Element is saved, S/4HANA simulates the outbound delivery (VL01N) and customer invoice (VF01) in the background.
b. It writes Predictive Journal Entries directly into ACDOCA under Extension Ledger 0E (stamping PS_PSP_PNR and PAOBJNR)!
c. As real invoices (VF01) are posted to Leading Ledger 0L, S/4HANA automatically posts offsetting reductions in Ledger 0E, allowing financial controllers to query ACDOCA (combining Ledger 0L Actuals + Ledger 0E Predictions) to see real-time Total Expected Project Revenue & Margin in standard Fiori apps!

Q23. Explain how SAP S/4HANA Service (CRM-S4 — Service Contracts & Service Orders) integrates with SAP PS Billing WBS Elements in hybrid Service-and-Project scenarios.

`ADVANCED`

Answer: In SAP S/4HANA, the legacy CS (Customer Service) module is modernized by S/4HANA Service (CRM-S4 — Tables CRMD_ORDERADM_H / I):

- Scenario A — Service Order Assigned to a PS WBS Element: When a field-service technician executes an S/4HANA Service Order (or Service Confirmation) that is account-assigned to a PS WBS Element, all spare parts, service products, and time confirmations post directly to ACDOCA with PS_PSP_PNR populated, rolling up into the WBS Element's EBRR PoC calculation or DP90/F4374 T&M billing queue!
- Scenario B — S/4HANA Service Contract Billing (Periodic) Funding a PS Maintenance Project: An S/4HANA Service Contract bills the customer monthly, posting actual revenue (Category 11) onto the linked Billing WBS Element while Maintenance/Service Orders collect the repair costs underneath that WBS hierarchy.

Structures (WBS & Networks)

Q24. What is the difference between a Project Definition and a WBS Element?

`BEGINNER`

Answer:

- Project Definition: The overarching umbrella or header record of a project. It holds default organizational data (Company Code, Controlling Area, Plant) and global parameters (Project Profile, Currency) that pass down to the rest of the structure. You cannot post costs directly to a Project Definition.
- WBS Element: The individual hierarchical building blocks (nodes) created underneath the Project Definition. WBS elements represent discrete phases, deliverables, or work packages, and act as the actual cost objects where budgets, planned costs, and actual postings are recorded.

Example: "C-1000" is the Project Definition for building a new corporate headquarters. Underneath it, "C-1000.01" (Foundation) and "C-1000.02" (Roofing) are the WBS Elements. When a vendor sends an invoice for cement, the Accounts Payable clerk posts the expense to WBS Element "C-1000.01", not the Project Definition.

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

Q25. Explain the three "Operative Indicators" on a WBS Element and their business significance.

`BEGINNER`

Answer: Located in the Basic Data tab of a WBS element, the Operative Indicators dictate what business transactions are permitted on that specific node:

- Planning Element: Allows the WBS element to be used for hierarchical cost and revenue planning (e.g., in transaction CJ40).
- Account Assignment Element (AAE): Allows actual costs (Purchase Orders, FI Invoices, Time Sheets) to be posted directly to the WBS element.
- Billing Element: Allows the WBS element to be linked to an SD Sales Order or Contract so that revenues and customer invoices can be posted against it.

Example: In a 3-level WBS hierarchy, Level 1 is flagged as the "Billing Element" (where the customer pays for the whole project). Level 2 is flagged as the "Planning Element" (where project managers estimate costs). Level 3 is flagged only as the "Account Assignment Element" (where engineers charge their daily timesheets and materials).

Q26. Explain the primary System Statuses in the lifecycle of a WBS Element or Network (CRTD, REL, TECO, CLSD).

`BEGINNER`

Answer: System statuses strictly control which business transactions are allowed at any stage of the project:

- CRTD (Created): Structure building, cost planning, and budgeting are allowed. Actual postings (POs, Goods Issues, Confirmations) and PR/Reservation generation are strictly blocked.
- REL (Released): The execution phase. Actual costs can be posted, PRs and Reservations are generated, and labor confirmations are allowed.
- TECO (Technically Completed): Logistics execution is finished. Open reservations and PRs are deleted, and no new purchase orders can be raised, but financial postings (like late vendor invoices and settlement) are still permitted.
- CLSD (Closed): The project is completely finished and settled to a zero balance. No logistical or financial postings are allowed.

Q27. How do "User Status Profiles" (OK02) work in SAP PS to enforce custom business workflows?

`INTERMEDIATE`

Answer: While System Statuses (CRTD, REL) are hardcoded by SAP, a User Status Profile allows a consultant to build a custom sequential approval or tracking workflow and assign it to the Project Profile or Network Type. Each User Status can be configured to automatically permit or forbid specific business transactions (e.g., blocking REL Release, blocking FI postings, or blocking PO creation).

Example: A company requires CFO approval before a project can be released. The consultant creates User Status Profile ZPROJ with two statuses: 10 - INIT (Initial) and 20 - APPR (Approved). Status 10 - INIT

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

is configured to forbid the "Release" business transaction. When a PM creates a project, it defaults to INIT; the "Release" button is blocked. Once the CFO reviews the budget, they change the User Status to APPR (secured via authorization code), which unlocks the ability to set the system status to REL.

Q28. Explain the difference between "Validations" (OPSI) and "Substitutions" (OPSN) in SAP PS structures, and how they are structured.

`INTERMEDIATE`

Answer: Both tools execute custom Boolean logic when a user saves a Project Definition, WBS, or Network, structured into three steps:

1. Prerequisite: The condition that must be true for the rule to trigger (e.g., Company Code = '1000').
2. Check (Validation) / Replacement (Substitution):
    - In a Validation, the system checks a second condition (e.g., Person Responsible <> ''). If false, the system throws a configured Warning or hard Error message, blocking the save.
    - In a Substitution, if the prerequisite is met, the system silently overwrites a target field with a new value or executes a custom ABAP user exit (e.g., Set Profit Center = 'PC_100').

Example: To ensure data quality, a Validation checks: Prerequisite: WBS Level = 1. Check: Investment Profile = '000001'. Message: "Error: Level 1 WBS must have Investment Profile 000001." A Substitution states: Prerequisite: Project Type = 'IT'. Replacement: Automatically populate the "Cost Center" field with 'CC_IT_ADMIN'.

Q29. How has the introduction of the Universal Journal (ACDOCA) in SAP S/4HANA changed the way WBS Elements are stored and reported in Financial Accounting?

`ADVANCED`

Answer: In classic SAP ECC, financial postings to a WBS element were split across FI tables (BSEG) and CO tables (COEP/COSP), requiring complex reconciliation. Furthermore, BSEG stored the internal 8-digit PROJK number, making direct SQL reporting difficult. In SAP S/4HANA, all actual postings are unified into the single Universal Journal (ACDOCA). Crucially, SAP included both the internal pointer and the external unmasked string directly as native columns on ACDOCA (specifically PS_PSP_PNR for the internal ID and PS_POSID for the external WBS string), alongside the Project Definition (PS_PRJ_PNR / PS_PSPID). This allows real-time, multidimensional HANA CDS views to aggregate project financials instantly without joining CO tables or running conversion exits at runtime.

Q30. Explain how the SAP PS Network Scheduling engine handles "Loop Detection" and "Reduction Strategies."

`ADVANCED`

Answer:

- Loop Detection: When relationships (FS, SS, FF, SF) are maintained between activities, a user might accidentally link Activity 30 back to Activity 10, creating an infinite chronological loop (10 -> 20 -> 30 -> 10). Before calculating dates, the scheduling engine runs a graph-theory traversal

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com

algorithm to detect cycles. If a loop is found, scheduling aborts with a hard error, and the user can use the "Loop Analysis" tool in CJ20N to highlight the exact conflicting relationships.

- Reduction Strategies: Configured in OPTI and assigned to Network Activities, a Reduction Strategy defines up to 6 progressive levels to artificially compress an activity's duration or wait times (Queue time, Move time) when backward scheduling violates the project's basic start date (or falls into the past). Instead of failing, the engine applies Level 1 (e.g., reduce queue time by 20%), then Level 2 (reduce duration by 10%), recalculating until the schedule fits the required window.

Sample Copy

Do not copy or sell this material, as it is the copyrighted property of www.sapsolutionlab.com
